<u>Aim</u>: Program for printing the string using procedure and macro.

Theory:

Procedures:-

- Procedures are used for large group of instructions to be repeated.
- Object code generated only once. Length of the object file is less the memory CALL and RET instructions are used to call procedure and return from procedure.
- More time required for its execution.
- Procedure Can be defined as:

Procedure name PROC

Procedure_name ENDP
Example:
Addition PROC near
Addition ENDP
Macro:-
• Macro is used for small group of instructions to be repeated.
• Object code is generated every time the macro is called.
Object file becomes very lengthy.
• Macro can be called just by writing.
• Directives MACRO and ENDM are used for defining macro.
• Less time required for its execution.
• Macro can be defined as:
Macro_name MACRO [Argument, , Argument N]
ENDM
Example:-
Display MACRO msg

ENDM

Implementation:

1. Program for printing the string using procedure

Program: org

```
100h
```

.data msg1 db 10,13,'Learning Procedure\$' msg2 db 10,13,'Procedure are funs\$' msg3 db 10,13,'Hello world\$'

.code

lea dx, msg1 call print

lea dx, msg2 call print

lea dx, msg3 call print mov ah, 4CH int 21h

print PROC mov ah,09h int 21h ret print ENDP RET

Output:

Conclusion:

Thus, the program for printing the string is successfully implemented using procedure and macro.

1. Differentiate between procedure and macros.

Aspect	Procedure	Macros
Parameterization	Accept parameters for dynamic behavior	Do not accept parameters, fixed values
Execution	Executed at runtime	Expanded at compile time
Scope	Typically have their own scope	No separate scope, expanded inline
Debugging Easier debugging at runtime		Can be challenging due to compile-time expansion
Flexibility	Dynamic behavior, runtime execution	Static behavior, compile-time customization
Usage	Used for reusable code blocks	Used for code generation and customization

2. Explain CALL and RET instructions.

CALL:

Initiates a subroutine or procedure by transferring control to a specified memory address. Saves the return address (the address of the instruction following the CALL) onto the stack before transferring control.

RET:

Returns control from a subroutine or procedure back to the calling code.

Retrieves the return address from the stack and sets the instruction pointer to that address, effectively resuming execution from the point where the subroutine was called.
